Sacramento River Vegetation Map

Pine Creek Example

Pine Creek Example

3-tiered Approach

- Geolocated Rapid Assessments
- Visual Check Using ArcPad
- Independent Digitization

Rapid Assessments

The rapid assessment protocol (RA) was developed by:

California Native Plant Society (*cnps.org*) and California Fish & Game (*dfg.ca.gov*) as a standardized method to quickly assess and

map vegetation types over relatively large, ecologically defined regions. Rapid assessments are used to determine ecological variation across landscapes, habitat composition, and site quality.

Rapid Assessments

We collected rapid assessments in areas that were not well represented by existing map units or defined vegetation classes.

Examples:

Herbaceous types: mugwort (Artemisia douglasiana)

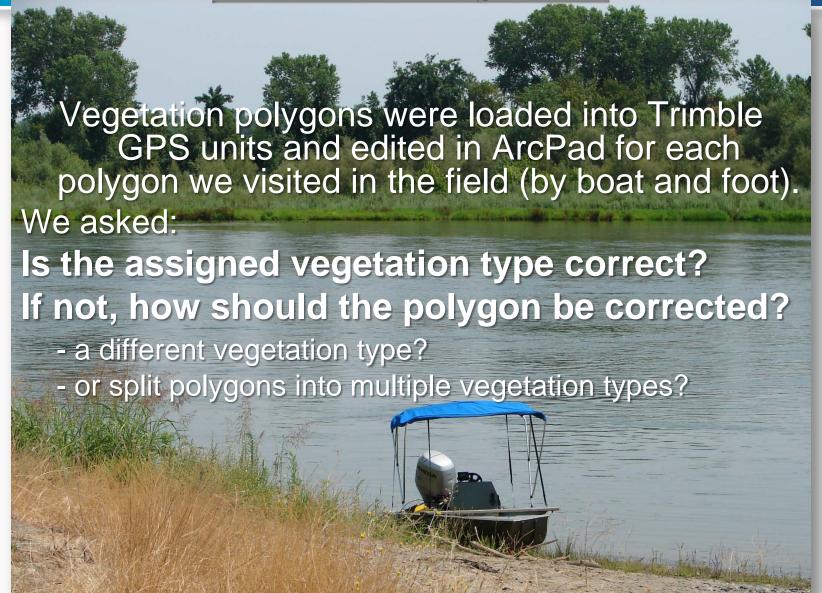

Forest types: white alder (*Alnus rhombifolia*)

Invasive species: fig (Ficus carica)

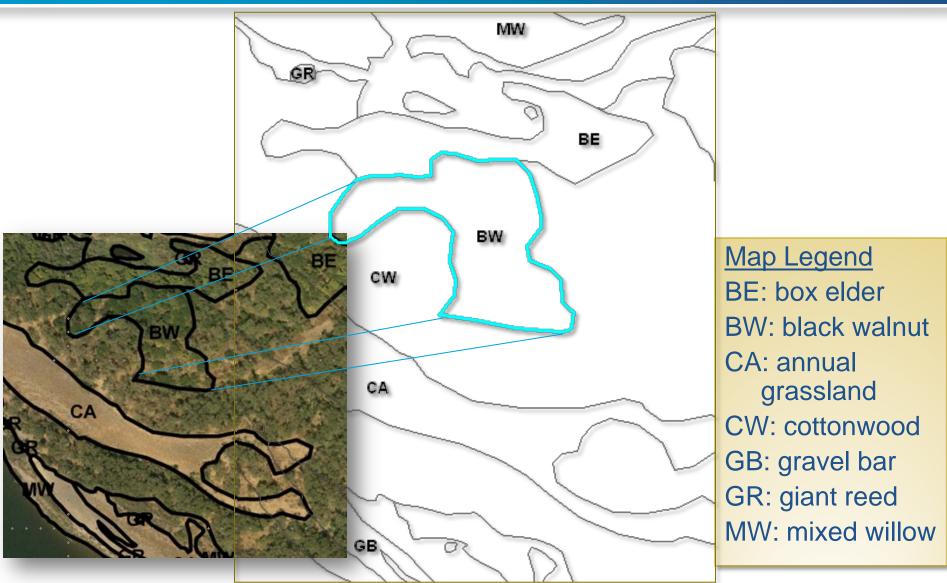

Visual Check using ArcPad

Visual Check using ArcPad

Results

Field Effort:

~ 15% of the total number of polygons (1,227)

>10% of all forest or herbaceous polygons

<10% of BS (blackberry), GR (giant reed), LP (*Ludwigia*), and OW (open water)

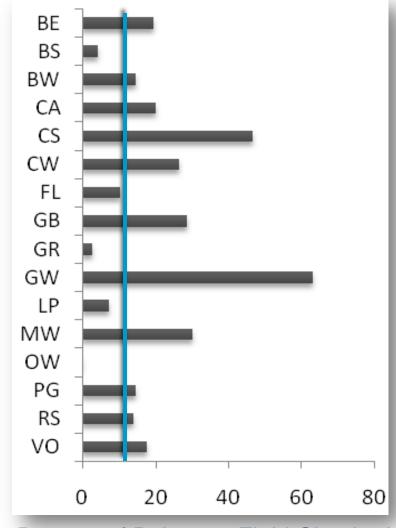

VegMap Field Check

Code	Category

Rapid Assessments using ArcPad Results

Total Accuracy: 85.3%

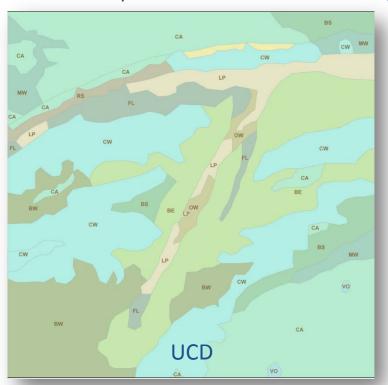

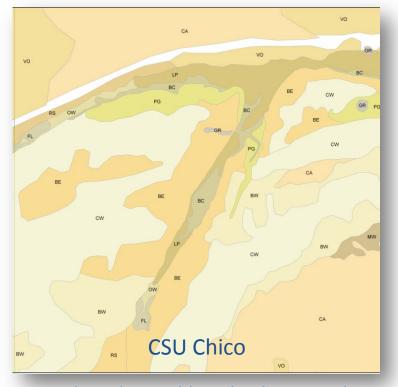

Independent Digitization

Re-digitized 500m by 500m blocks of riparian vegetation

3,300 hectares re-digitized (or 132 blocks)

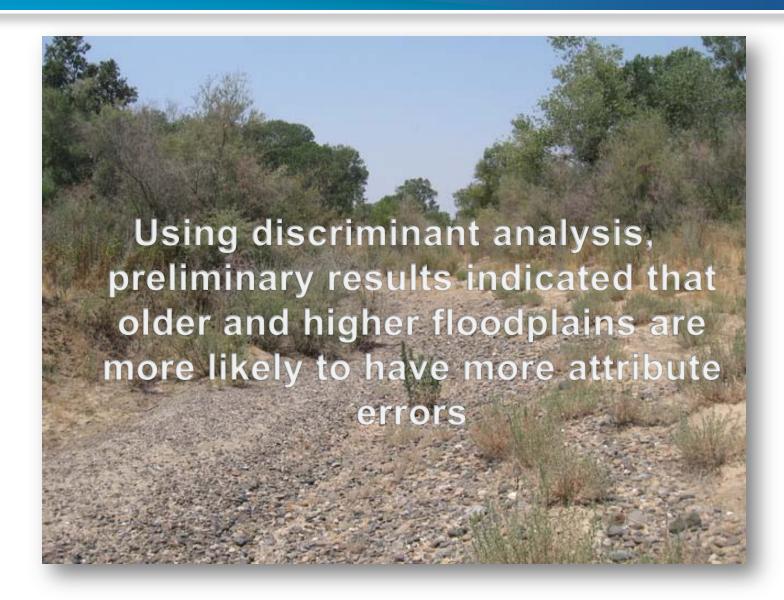

Found limited differences in polygon size by vegetation class with paired comparisons Cottonwood Forest (CW) displayed the greatest difference in area

Environmental Variables

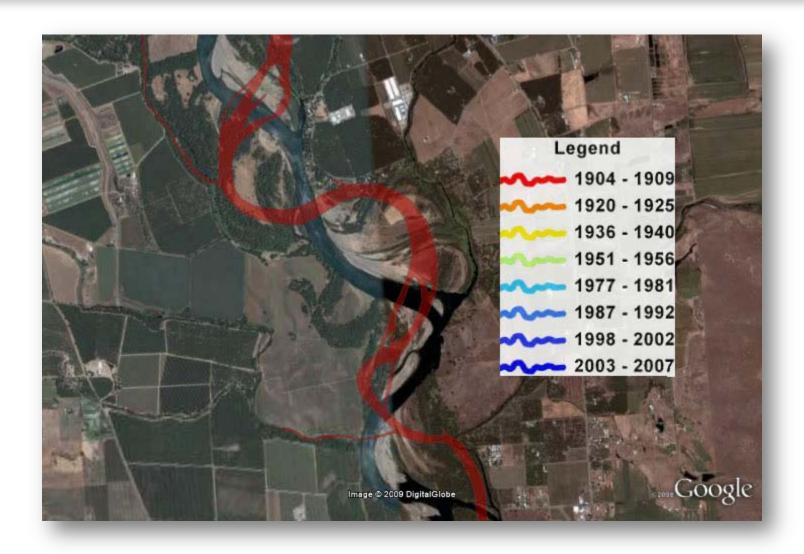

Dynamic Riverscapes

Recursive Partition Analysis

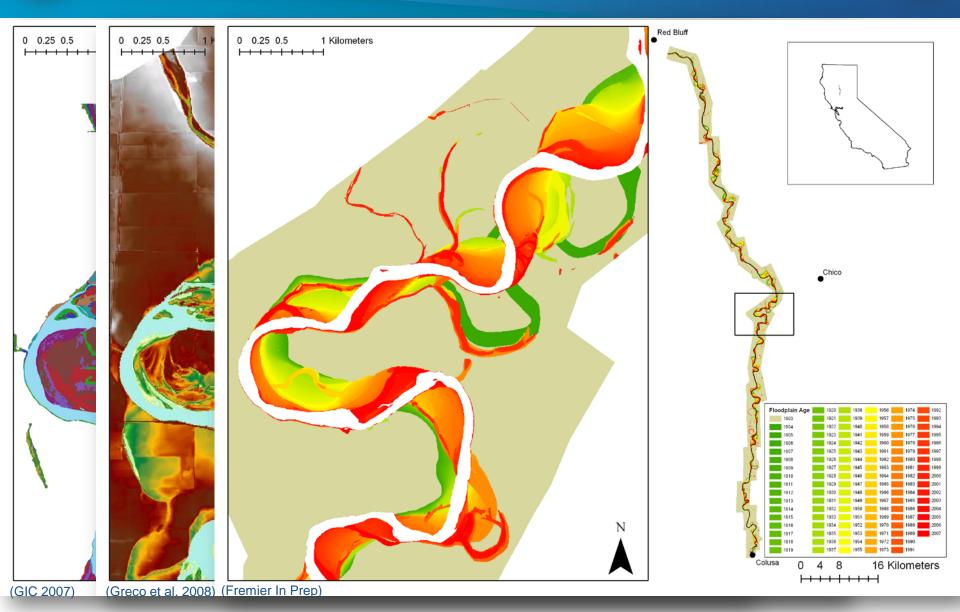

Variable	Description					
LnArea	Ln transformed polygon area					
Normal PA Ratio	Normalized perimeter to area ratio where /)					
Channel Distance	Distance from polygon centroid to main channel					
Levee Distance	Distance from polygon centroid to levee					
Relative Elevation Range	Range of relative elevation values					
Relative Elevation Median	Median relative elevation value					
Relative Elevation	Minimum relative elevation value					
Minimum						
Floodplain Age Range	Range of floodplain age values					
Floodplain Age Median	Median floodplain age					
Floodplain Age Maximum	Maximum floodplain age					
Height	Polygon Height Class: 1:<2m, 2:2-6m, 3:6-10m,					
	4:10-20m, 5:>20m.					

Riverscape Ecology

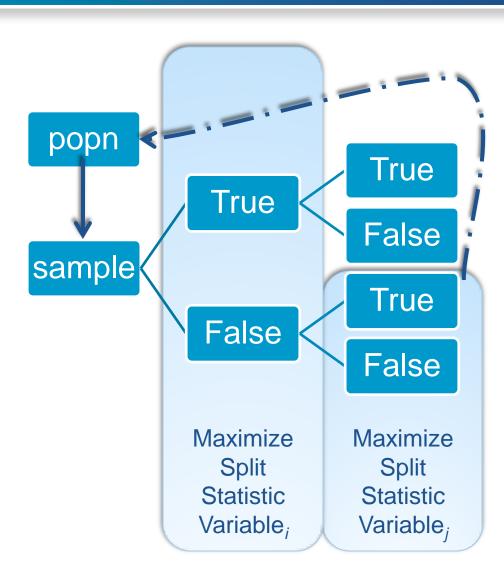

Statistical Partitioning

- Recursive partitioning
- Classification & Regression Trees (CART)
- Random Forests

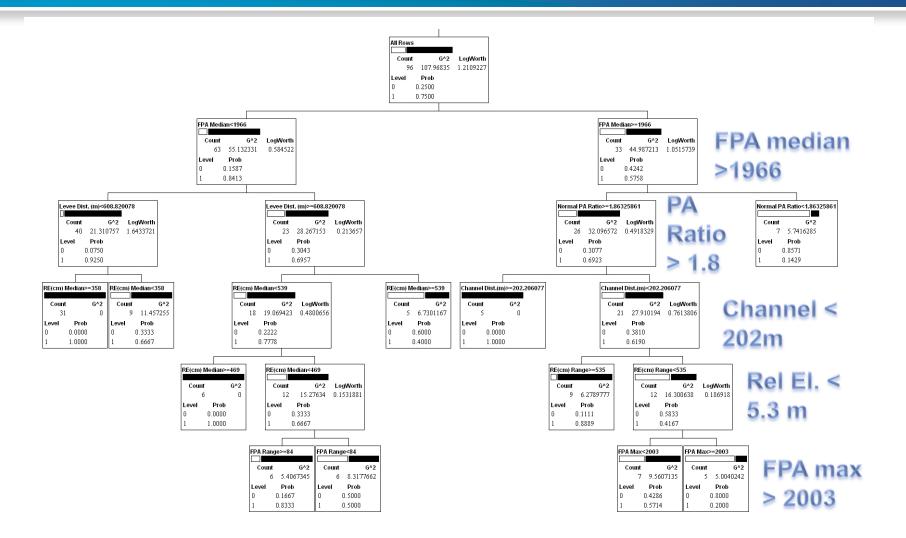

Continuous & Categorical Independent Variables

Riparian Scrub (RS)

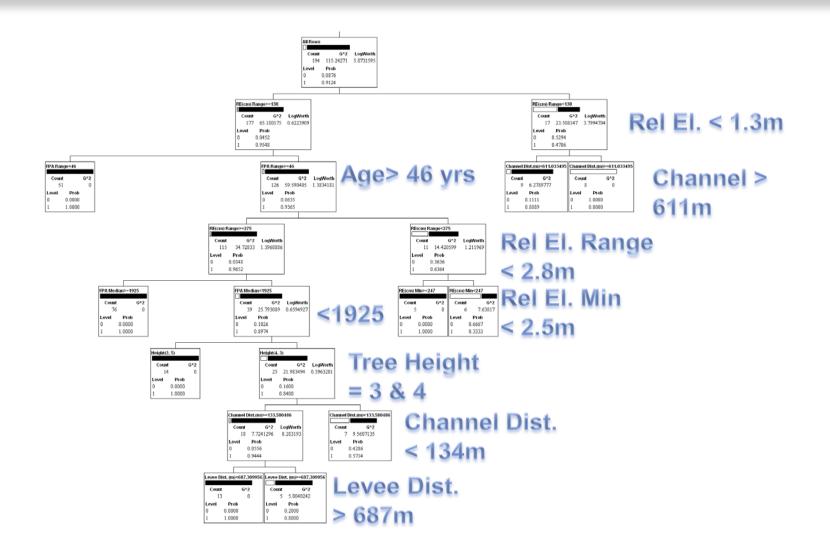

Cottonwood (CW)

Likelihood of vegetation class correctness as determined by the probability value produced by the recursive partition model.

SRMAP Class Code	n (# polys)	Likely Correct n	Likely Misclass n	Likely Correct ha	Likely Misclass ha	R ²	# of Splits	k-fold

PG PERENNIAL GRASSES	34	211	52	77.7	26.2	0.32	3	0.13
RS RIPARIAN SCRUB	96	546	213	687.1	288.8	0.46	10	0.27
VO VALLEY OAK	109	559	244	831.0	711.6	0.59	12	0.45

Likely misclassified polygons were identified if they had a >0.5 probability of being incorrectly classified based on the model variables.

Conclusions

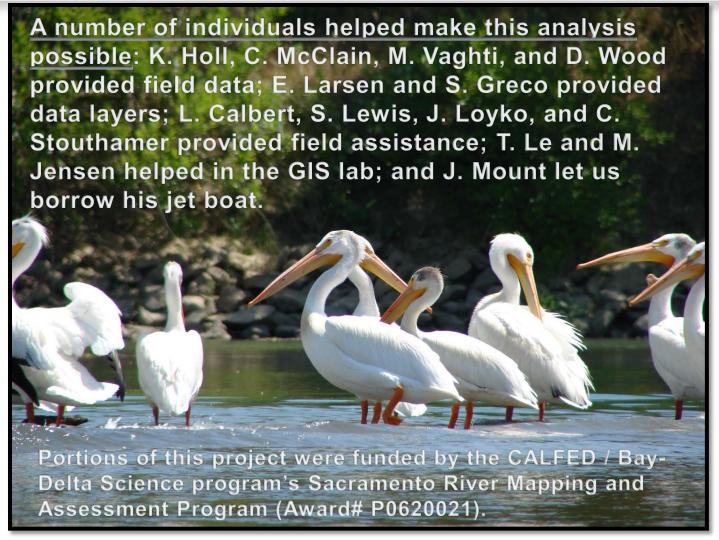

- Digitized maps from interpreted aerial imagery will continue to be used, most often because of limitations in resources and expertise, especially in retrospective studies.
- Ancillary datasets, particularly in riverscape ecology, can be used to leverage insights to the spatial context of mapping errors.
- Recursive partitioning is one robust method for crafting type-specific solution sets that combines continuous and categorical spatial data, which can be used to:
 - 1.ascertain the nature of errors for potential correction (e.g., training sets to fine tune interpretation),
 - 2.guide map users in interpretation and utility (e.g., removing erroneous polygons from analysis), and
 - 3.place bounds of confidence around any change detection analyses that are computed from such maps.

or just make more accurate maps!
